

# Integral Equations Notes: [457]

[Drew Remmenga]

June 10, 2024

**Definition 1.** *An integral equation is any equation in which the unknown function is inside the integral sign.*

**Example 1.**

$$\int_a^b k(x, y)u(y)dy = f(x), x \in (a, b)$$

Here  $k$  and  $f$  are given and  $u(x)$  is the unknown function.

**Example 2.**

$$\int_0^\infty e^{-xt}u(t)dt = f(x), x \in (0, \infty)$$

$f(x)$  is the laplace transform of  $u$ .

**Remark 1.** *There is an inversion formula giving  $u$  from  $f$  but it involves an integrall of  $f(x)$  over complex values of  $x$ . In practice we may only know  $f(x)$  for real values of  $x$ .*

**Example 3.**

$$\int_{-1}^1 u(t)dt = 1$$

One solution

$$u(t) = \frac{1}{2}, t \in (-1, 1)$$

Clearly there are lots of solutions, e.g.

$$u(t) = \frac{1}{2} +$$

any odd function of  $t$ .

or

$$u(t) = \frac{1}{2} + \sum_{n=1}^{\infty} \{a_n \cos(nt\pi) + b_n \sin(nt\pi)\}$$

For any reasonable  $a_n$  and  $b_n$ .
